## 1. INTRODUCTION

In this paper we set out to analyse an open conjecture in a modern graph theory problem known as rich-neighbor edge coloring.

**Definition 1.1.** In an edge coloring, an edge  $e$  is called *rich* if all edges adjacent to  $e$  have different colors. An edge coloring is called a *rich-neighbor edge coloring* if every edge is adjacent to some rich edge.

**Definition 1.2.**  $X'_{rn}(G)$  denotes the smallest number of colors for which there exists a rich-neighbor edge coloring.

**Conjecture 1.3.** For every graph  $G$  of maximum degree  $\Delta$ ,  $X'_{rn}(G) \leq 2\Delta - 1$  holds.

**Example 1.4.** Let's take a look at the Petersen graph and an example of a rich-neighbor edge coloring.

We can see that for the Petersen graph (which is 3-regular) we can find an appropriate coloring with 5 colors so  $X'_{rn} \leq 5 \leq 2 \cdot 3 - 1 = 5$ . This shows that the conjecture holds for this graph.  $\diamond$

## 2. ALGORITHMS

## 2.1. INTEGER PROGRAMMING

Using SageMath we constructed an integer programming model that finds a rich-neighbor edge coloring for a given graph using the smallest number of colors possible. Our interger program looks like this:

minimize $t$	we minimize the number of colors we need
subject to $\forall e: \sum_{i=1}^{2\Delta-1} x_{ei} = 1$	each edge is exactly one color

$$\forall i \forall u \forall v, w \sim u, v \neq u : \quad x_{uv,i} + x_{uw,i} \leq 1$$

edges with the same vertex are a different color

$\forall e \forall i: \quad x_{ei} \cdot i \leq t$  we use less or equal to  $t$  colors

$$\forall i \ \forall uv \ \forall w \sim u, w \neq v \ \forall z \sim v, z \neq u, w : \quad x_{uw,i} + x_{vz,i} + y_{uv} \leq 2$$

$$uv \text{ is a rich edge} \Leftrightarrow \text{all adjacent edges are a different color}$$

$$\forall e: \quad \sum_{f \sim e} y_f \geq 1 \quad \text{every edge is adjacent to some rich edge}$$

$$\forall e: \quad 0 \leq y_e \leq 1, y_e \in \mathbb{Z}$$

$$\forall e \forall i : \quad 0 \leq x_{ei} \leq 1, x_{ei} \in \mathbb{Z},$$

where

$$x_{ei} = \begin{cases} 1, & \text{if edge } e \text{ has color } i \\ 0, & \text{otherwise} \end{cases} \quad \text{and} \quad y_e = \begin{cases} 1, & \text{if edge } e \text{ is rich} \\ 0, & \text{otherwise.} \end{cases}$$

In our implementation of the ILP we fix the number of colors to  $2\Delta - 1$  by adding the following constraint

$$t = 2\Delta - 1,$$

since the coloring can't be made with less colors (every edge has  $2\Delta - 2$  neighboring edges and the edge itself has to be a different color) and any more colors do not satisfy the conjecture. Therefore we only check if the program has a solution that satisfies all the constraints and the conjecture. In theory this doesn't make the program faster, but in our practice tests it did make a significant difference.

Our implementation of the IPL is demonstrated in the following code.

## 2.2. ITERATIVE ALGORITHM

We debated implementing an iterative algorithm that finds a rich neighbor edge coloring, but we weren't able to come up with anything that runs in polynomial time. From [1] we know that integer linear programs are NP-complete problems, so it didn't make much sense implementing a slower algorithm.

## 3. COMPLETE SEARCH

As illustrated in Table 1, the number of  $k$ -regular graphs on  $n$  vertices is of exponential growth. This poses a computational challenge, as checking all graphs becomes impossible for larger values of  $n$ . However, we can still check all graphs for smaller values of  $n$  up to 15.

Vertices	Degree 4	Degree 5	Degree 6	Degree 7
5	1	0	0	0
6	1	1	0	0
7	2	0	1	0
8	6	3	1	1
9	16	0	4	0
10	59	60	21	5
11	265	0	266	0
12	1544	7848	7849	1547
13	10778	0	367860	0
14	88168	3459383	21609300	21609301
15	805491	0	1470293675	0
16	8037418	2585136675	113314233808	733351105934

TABLE 1. Number of  $k$ -regular graphs on  $n$  vertices

## 3.1. GRAPH GENERATION

Graphs for the complete search were taken from a collection of `.tex` files, provided by Professor Skrekovski. The files contain all  $k$ -regular graphs on  $n$  vertices up to 15 vertices.

## 4. RANDOM SEARCH

In addition to examining the hypothesis for smaller graphs, we were also interested in checking if the conjecture holds for larger graphs. The challenge is, as said before, testing all colorings in graphs with many vertices.

Recognizing the enormity of this task, a random search algorithm seemed a natural continuation of our problem. Here we opted for a modification approach.

We start with a random graph, check if the conjecture holds and then modify it in a way that preserves the regularity and connectedness. We repeat this process indefinitely, well, until we stop our program. Since, if a rich-neighbor edge coloring exists in a given graph there is a bigger probability that it also exists in similar graphs, therefore, on every iteration, there is a small probability that we generate a completely new random graph and start again.

Written below is the algorithm for modifying graphs. First it selects two random edges and deletes them. Then it generates a random number  $p$  from  $[0, 1)$  and based on the value of  $p$  it adds back two different edges we did not have before. It repeats this until it gets a connected modified graph.

---

**Algorithm 2:** tweak

---

**Input:** Graph  $G$   
**Output:** Tweaked graph  $T$   
 $T \leftarrow \text{graph.copy}()$   
 $e_1 \leftarrow T.\text{random\_edge}()$   
 $u_1, v_1, \text{extra}_1 \leftarrow e_1$   
 $T.\text{delete\_edge}(e_1)$   
 $e_2 \leftarrow T.\text{random\_edge}()$   
 $u_2, v_2, \text{extra}_2 \leftarrow e_2$   
 $T.\text{delete\_edge}(e_2)$   
 $p \leftarrow \text{random}()$   
**if**  $p < 0.5$  **then**  
     $T.\text{add\_edge}(u_1, u_2)$   
     $T.\text{add\_edge}(v_1, v_2)$   
**else**  
     $T.\text{add\_edge}(u_1, v_2)$   
     $T.\text{add\_edge}(v_1, u_2)$   
**if** *not*  $T.\text{is\_connected}()$  **then**  
    **return** tweak( $G$ )  
**return**  $T$

---

#### 4.1. GRAPH GENERATION

Since we only need one graph to start our iterative process, we can generate it randomly using the built in sage function `graphs.RandomRegular`.

### 5. CHECKING THE COLORING

dodaj še opisa algoritmov

---

**Algorithm 3:** Check Coloring

---

**Input:** Graph  $G$ , Coloring  $coloring$

**Output:** Boolean indicating proper coloring

```
for  $v$  in  $G.vertices()$  do
     $col \leftarrow \text{set}()$ 
    for  $w$  in  $G.neighbors(v)$  do
        for  $i$  in  $\text{range}(1, 2 \cdot G.degree()[0])$  do
            if  $coloring[(\text{Set}((v, w)), i)] = 1$  then
                 $col.add(i)$ 
        if  $\text{len}(col) \neq \text{len}(G.neighbors(v))$  then
            return False
    return True
```

---

---

**Algorithm 4:** Check Richness

---

**Input:** Graph  $G$ , Rich edges  $richEdges$

**Output:** Boolean indicating proper rich-neighbor edge coloring

```
for  $(u, v)$  in  $G.edges(labels = False)$  do
     $S \leftarrow 0$ 
    for  $w$  in  $G.neighbors(u)$  do
        if  $w = v$  then
             $S \leftarrow S + richEdges[\text{Set}((u, w))]$ 
    for  $z$  in  $G.neighbors(v)$  do
        if  $z = u$  then
             $S \leftarrow S + richEdges[\text{Set}((v, z))]$ 
    if  $S = 0$  then
        return False
    return True
```

---
