1. Introduction

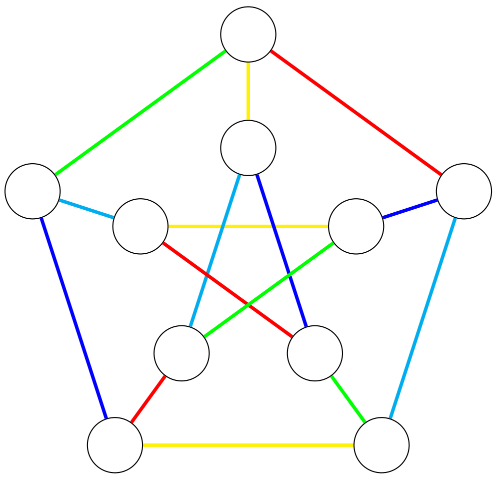
In this paper we set out to analyse an open conjecture in a modern graph theory problem known as rich-neighbor edge coloring.

Definition 1.1. In an edge coloring, an edge e is called *rich* if all edges adjacent to e have different colors. An edge coloring is called a *rich-neighbor edge coloring* if every edge is adjacent to some rich edge.

Definition 1.2. $X'_{rn}(G)$ denotes the smallest number of colors for which there exists a rich-neighbor edge coloring.

Conjecture 1.3. *For every graph G of maximum degree Δ, $X'_{rn}(G) \leq 2\Delta - 1$ holds.*

Example 1.4. Let's take a look at the Petersen graph and an example of a rich-neighbor edge coloring.



We can see that for the Petersen graph (which is 3-regular) $X'_{rn} \leq 5$. ♢

2. Plan

Our plan is to create an integer program that "proves" the conjecture for (small) regular graphs of degree $4 \geq$ (it finds a rich-neighbor edge coloring for every k-regular graph on n verticies) and to make a random search algorythm for checking classes of graphs that are too large to be checked individually.

2.1. **Integer Programming.** Using SageMath we plan to create an integer programming model, that checks all smaller graphs for a rich-neighbor edge coloring with $\leq 2\Delta - 1$ colors. Our interger program looks like this:

$$\text{minimize } t \qquad \text{we minimize the number of colors we need}$$

$$\text{subject to } \forall e: \quad \textstyle\sum_{i=1}^{k} x_{ei} = 1 \qquad \text{each edge is exactly one color}$$

$$\forall i\ \forall u\ \forall v, w \sim u, v \neq u: \quad x_{uv,i} + x_{uw,i} \leq 1$$
$$\text{edges with the same vertex are a different color}$$

$$\forall e\ \forall i: \quad x_{ei} \cdot i \leq t \qquad \text{we use less or equal to } t \text{ colors}$$

$$\forall i\ \forall uv\ \forall w \sim u, w \neq v\ \forall z \sim v, z \neq u, w: \quad x_{uw,i} + x_{vz,i} + y_{uv} \leq 2$$
$$uv \text{ is a rich edge} \Leftrightarrow \text{all adjacent edges are a different color}$$

$$\forall e: \quad \textstyle\sum_{f \sim e} y_f \geq 1 \qquad \text{every edge is adjacent to some rich edge}$$

$$\forall e: \quad 0 \leq y_e \leq 1,\ y_e \in \mathbb{Z}$$

$$\forall e\ \forall i: \quad 0 \leq x_{ei} \leq 1,\ x_{ei} \in \mathbb{Z},$$

where

$$x_{ei} = \begin{cases} 1, & \text{if edge } e \text{ has color } i \\ 0, & \text{otherwise} \end{cases} \quad \text{and} \quad y_e = \begin{cases} 1, & \text{if edge } e \text{ is rich} \\ 0, & \text{otherwise.} \end{cases}$$

We will determine at what point the computation of rich-neighbor edge coloring becomes too intense for this technique and we will then use the random search algorythm.

2.2. **Random Search.** We will construct a random search algorythm that will check if the conjecture holds for a class of graphs that are too large to be checked individually. We plan to iterate over all k-regular graphs on n-vertices and based on the generated sample of

$$X \sim \begin{pmatrix} 0 & 1 \\ 1-p & p \end{pmatrix}$$

for a small p we will check the graph or not. Since the conjecture should hold for all graphs, we will determine the value p so that we check approximately the same number of graphs for each k and n.
